## ABSTRACT

The compounds used in this study, TET and OXM, were tested in vitro for their antibacterial activities against isolated strains from the hospital environment (*S. aureus* H, *E. coli* H and *K. pneumoniae* H) and reference strains (*S. aureus* A, *E. coli* A, *B. subtilis* A and *P. aeruginosa* A). The calculation of the MBC/minimum inhibitory concentration ratio of the products TET and OXM showed that the two products have a bactericidal effect on the strains tested.

**Keywords:** Antibacterial activity Tetrazole Oxime. Strains

## 1. Introduction

### Result and discussion

Microorganisms, whether they originate from humans or the environment, contaminate the hospital environment. 1 The quality and quantity of this contamination changes with time, across different establishments, and even within the same institution in relation to the services, patients, treatment, and practices that are practiced. True ecological niches, the hospital environment is home to a vast variety of microorganisms. 2 Contamination by these microbes is pervasive, and controlling it requires stringent, complicated, and costly processes. There may not be a way to quantify the role of the hospital's physical layout in the spread of infection, but there's no denying that bio-contamination poses a serious threat to vulnerable patients, healthcare workers, and areas where invasive procedures are performed. A phenomenon known as acquired resistance may occur in microbes when they become resistant to certain antimicrobial treatments. A major issue in public health is the development of antibiotic and cleaning product resistance in bacteria. A major

contributor to the alarming rise in hospital-acquired infections is the transmission of multiresistant bacteria amongst sick, frail patients. 3-4 In order to address this issue, we need to discover other ways to utilize antibiotics. The development of novel compounds via chemical synthesis or the identification of naturally occurring chemicals, especially essential oils, that possess antibacterial characteristics would be very beneficial and intriguing. Within this context, the antimicrobial activity of two tetrazole-derived synthetic chemical compounds against hospital-acquired strains was investigated. The tetrazole derivatives' wide range of potential uses has piqued a lot of interest in them. 5 Our team identified strains 2-6 of *Escherichia coli*, *Staphylococcus aureus*, and *Klebsiella pneumoniae* in hospital environments, and we were interested in studying the antibacterial activity of two synthesized compounds derived from tetrazole against these strains.

### 1.1. Demonstration of the antibacterial activity

The antibacterial activity of the tetrazole derivatives (by disc diffusion method) was evaluated on the seven strains tested. The diameters of the aureoles of inhibition were measured in millimetre (mm). The results obtained are shown in [Table 1](#).

**Table 1** Diameters of the zones of inhibition of the Tetrazole derivatives in (mm)

	TET	OXM	Positive Witness
<i>S. aureus</i> H	<8	8 ± 0	26
<i>S. aureus</i> A	<8	9 ± 0,6	26
<i>E. coli</i> H	<8	11 ± 0	25
<i>E. coli</i> A	<8	15 ± 0	27
<i>K. pneumoniae</i> H	<8	9,66 ± 0,6	27
<i>B. subtilis</i> A	<8	9,33 ± 0,6	24
<i>P. aeruginosa</i> A	9±0	12,33 ± 0,6	25

Strains A: ATCC strains; Strains H: strains isolated from the hospital environment; Positive Control: Chloramphenicol (30 µg/mL).

The OXM product has an inhibiting activity against all of the strains studied, with an inhibition diameter ranging from 8 to 15 mm: *Escherichia coli* A. (15 mm), *Pseudomonas aeruginosa* A. (12.33 mm), *Escherichia coli* H. (11 mm), *Bacillus subtilis* A. (9.33 mm), *Klebsiella pneumoniae* H. (9.66 mm), *Staphylococcus aureus* A (9 mm) and *Staphylococcus aureus* H (8 mm). The TET product showed no activity against all strains tested, except for the *Pseudomonas aeruginosa* A strain which was found to be not very sensitive with a diameter of 9 mm (Table 2). The results of the antibiogram showed that all strains tested are sensitive to Chloramphenicol, with inhibition diameters ranging from 24 to 27 mm.

**Table 2** Minimum inhibitory concentration of the TET product

Concentration (mg/mL)	2,5	1,25	0,62	0,31	0,15	0,07	0,03	0,01	Witness
<i>Staphylococcus aureus</i> A	-	-	+	+	+	+	+	+	+
<i>Staphylococcus aureus</i> H	-	+	+	+	+	+	+	+	+
<i>Escherichia coli</i> A	-	-	+	+	+	+	+	+	+
<i>Escherichia coli</i> H	-	+	+	+	+	+	+	+	+
<i>Klebsiella pneumoniae</i> H	-	+	+	+	+	+	+	+	+
<i>Bacillus subtilis</i> A	-	-	+	+	+	+	+	+	+
<i>Pseudomonas aeruginosa</i> A	-	-	+	+	+	+	+	+	+

Strains H: strains isolated from the hospital environment; Strains A: ATCC strains.

**Table 2** Minimal inhibitory concentrations of the OXM product

Concentration (mg/mL)	2	1	0,5	0,25	0,12	0,06	0,03	0,01	Witness
<i>Staphylococcus aureus</i> A	-	-	+	+	+	+	+	+	+
<i>Staphylococcus aureus</i> H	-	-	+	+	+	+	+	+	+
<i>Escherichia coli</i> A	-	-	-	+	+	+	+	+	+
<i>Escherichia coli</i> H	-	-	+	+	+	+	+	+	+
<i>Klebsiella pneumoniae</i> H	-	-	+	+	+	+	+	+	+
<i>Bacillus subtilis</i> A	-	-	-	-	+	+	+	+	+
<i>Pseudomonas aeruginosa</i> A	-	-	-	-	+	+	+	+	+

Strains H: strains isolated from the hospital environment; Strains A: ATCC strains.

It was noted that the two products TET and OXM have showed a weak antibacterial activity compared to the antibiotic tested (**Table 1**).

The results of the inhibiting activity of the synthetic chemical product OXM corroborate with the work of Dhayanithi et al.<sup>7</sup> Indeed, these authors have shown that some derived products of tetrazole substituted by the benzyl group have an inhibiting activity against strains of *E. coli* (going from 10 to 11 mm), *S. aureus* (from 11 to 13 mm) and *B. subtilis* (from 11 to 12 mm). Other tetrazole derivatives gave important antibacterial activities against the strains tested: *E. coli* (ranging from 22 to 24 mm), *B. subtilis* (from 21 to 23 mm) and *S. aureus* (from 15 to 20 mm), with the exception of *K. pneumoniae* and *P. aeruginosa* (less than 10 mm).

The results of the inhibiting activity of chemical product TET show that the majority of strains tested appeared resistant to chemical product TET. These results are in agreement with works of Dhayanithi, which showed that chemical products derived from tetrazole do not have any antibacterial activity or have a weak inhibiting activity ( $\leq 10$  mm) against the strains studied.<sup>7</sup> Thus, one could deduce that the antibacterial activity of the products that we tested varies according to the substituents or the radicals related to the cycle tetrazole which can modify its chemical properties (hydrophobicity...) while influencing its mode of action.

### 1.2. Determination of minimum inhibitory concentrations

**Table 4** Minimum bactericidal concentration of the TET product (phenyl)-1*H*-tetrazole (TET) and its precursor

Concentration (mg/mL)	2.5	1.25
<i>Staphylococcus aureus</i> A	-	+
<i>Staphylococcus aureus</i> H	+	+
<i>Escherichia coli</i> A	-	+
<i>Escherichia coli</i> H	+	+
<i>Klebsiella pneumoniae</i> H	+	+
<i>Bacillus subtilis</i> A	-	+
<i>Pseudomonas aeruginosa</i> A	-	+

The results of the MIC of the TET and OXM tetrazole derivatives are shown in **Tables 2 and 3**. The MIC is the lowest concentration that showed no bacterial growth. The results in **Table 2** show that the TET product has a low inhibitory activity on strains of *S. aureus* A, *E. coli* A, *B. subtilis* A and *P. aeruginosa* A, with a MIC of about 1,25 mg/mL. The strains isolated from the hospital environment, namely *E. coli* H, *S. aureus* H and *K. pneumoniae* H, showed greater resistance to TET, with a MIC of 2.5 mg/mL (**Table 2**).

**Table 5** shows that the MBCs of product OXM vary from 0.5 mg/mL against *P. aeruginosa* A to 1 mg/mL against *E. coli* A and *B. subtilis* A. The strains *S. aureus* A, *E. coli* H and *K. pneumoniae* showed resistance opposite the OXM, with an MBC of 2 mg/mL. The strain *S. aureus* H showed strong resistance, with an MBC higher than 2 mg/mL (**Table 5**).

The works of Rao et al.<sup>8</sup> showed that the MBCs of tetrazole derivatives ranged from 0.5 to 1 mg/mL against *S. aureus* and *B.*

*subtilis* strains<sup>9</sup>, the MBC against *E. coli* is on the order of 6.25 mg/mL.

Strains H: strains isolated from the hospital environment; Strains A: ATCC.

**Table 5** Minimum bactericidal concentration of the OXM product

Concentration (mg/mL)	2	1	0.5	0.25
<i>Staphylococcus aureus</i> A	-	+	+	+
<i>Staphylococcus aureus</i> H	+	+	+	+
<i>Escherichia coli</i> A	-	-	+	+
<i>Escherichia coli</i> H	-	+	+	+
<i>Klebsiella pneumoniae</i> H	-	+	+	+
<i>Bacillus subtilis</i> A	-	-	+	+
<i>Pseudomonas aeruginosa</i> A	-	-	-	+

#### 4.2. Biology

**Fig 1.** Compounds used in antibacterials Strains H: strains isolated from the hospital environment; Strains A: ATCC.

The calculation of the MBC/MIC ratio of the products TET and OXM showed that the two products have a bactericidal effect on the strains tested.

## 2. Conclusion

The aim of this work was to study the antibacterial activity of two tetrazole derivatives, TET and OXM, against isolated strains of the hospital environment and reference strains. The evaluation of the antibacterial activity of the OXM product using the disk diffusion method showed an inhibitory activity against all of the studied strains: *Escherichia coli* A (15 mm), *P. aeruginosa* A (12.33 mm), *E. coli* H (11 mm), *B. subtilis* A (9.33 mm), *K. pneumoniae* H (9.66 mm), *S. aureus* A (9 mm) and *S. aureus* H (8 mm). Indeed, the OXM product has an important activity against strains tested, with MIC ranging from 0.25 to 2 mg/mL. The TET product showed no antibacterial activity against the strains studied, except for *P. aeruginosa* which showed a low sensitivity of 9 mm. The MICs of the TET product range from 1.25 to 2.5 mg/mL. Moreover, the results of MBC of the products tested showed that the two products have a bactericidal effect against the strains tested. Finally, as a perspective of this work, the products derived from tetrazole can be modified chemically or combined with other molecule credits in order to increase their spectrum of activity or to test their effects on cell cultures.

## 3. Materials and methods

### 3.1. Chemistry

In these compounds, an electron-withdrawing group 5-(4-chloro) is replaced for a tetrazole at position 5. - A

The research was place from January 18th to May 20th, 2016, at the Biotechnology Laboratory of the Faculty of Sciences at Sidi Mohamed Ben Abdellah University-Fez. We selected strains 2–6 that were found in a hospital setting: *Escherichia coli*, often known as *E. coli* H These include *Staphylococcus aureus* and *Klebsiella pneumoniae*. The ATCC reference strains were obtained, purified, and kept at -80°C at the Fez-Boulmane region's Regional Laboratory for Epidemiological Diagnosis and Environmental Health (LRDEHM). These are the bacteria that may be found in the laboratory: *Staphylococcus aureus* (A), *Escherichia coli* (A), *Bacillus subtilis* (A), and *Pseudomonas aeruginosa* (A). The strains were subcultured on Luria Bertani medium (LB) until they were exhausted, and then incubated at 37°C for 24 hours. Bringing attention to antimicrobial action: antibiogram

The antibiogram, also known as the diffusion technique, is a popular tool in medical analysis labs and one of the first ways to find out which bacteria are sensitive to certain medicines. Both the National Committee for Clinical Laboratory Standards and the European Committee for Antibacterial Susceptibility Testing 10 recommend it. 11

### 3.2. 1. Principle

This method consists in depositing a disk impregnated

with the antibacterial agent in a Petri dish previously seeded by specific bacterial species. The agent will diffuse into the agar, creating a halo of growth inhibition of the bacteria around the disc. Antibacterial activity by disk diffusion of the synthetic chemicals tested, TET and OXM, was performed according to the protocol recommended by EUCAST and CLSI, with some modifications.<sup>10-11</sup>

#### □ *Preparation of solutions of derivatives of tetrazole*

10 mg samples of the chemicals, TET and OXM, were dissolved in 400  $\mu$ L of DMSO to obtain a final concentration of 25 mg/mL.

#### □ *Preparation of the inoculum*

From a pure bacterial culture of 24 h on LB medium, three to four colonies were removed with the aid of a loop and then transferred into 4 mL of sterile physiological saline (0.9%). The bacterial suspension was homogenised. The turbidity of the bacterial suspension was adjusted to that of the McFarland 0.5 standard, which corresponds to an inoculum of a bacterial load of approximately  $1 \times 10^8$  CFU/mL for *Escherichia coli*.<sup>11</sup>

#### □ *Inoculation of boxes*

Inoculation was performed on Mueller Hinton medium (Appendix 4) by swabbing. A sterile cotton swab was plunged in the bacterial suspension. Excess liquid was removed by rotating the swab on the walls of the tube. Spreading out on limps is performed by tight streaks on the agar surface in three directions.

#### □ *Deposit of the discs*

Discs of paper Whatman, N°1 with a diameter of 6 mm were prepared and autoclaved for 20 min at 121°C. The discs were then soaked in 10  $\mu$ L of TET or OXM solutions. They were then firmly deposited on the surface of the dishes inoculated with the bacterial strains tested (*S. aureus* H, *E. coli* H, *K. pneumoniae* H, *S. aureus* A, *E. coli* A, *B. subtilis* A and *P. aeruginosa* A). The discs soaked in Chloramphenicol (30  $\mu$ g/mL) were used as positive witnesses. The negative witness is a disc containing 10  $\mu$ L of DMSO. The dishes were incubated at 37°C for 24 h. Each test was carried out in three repetitions.

After 24 h of incubation, the product endowed with an antibacterial activity formed a halo of growth inhibition of the bacteria around the disc. Inhibition diameters were measured in (mm) disc inclusive.

### **3.3. Determination of the minimum inhibitory concentration in liquid medium**

The minimum inhibitory concentration (MIC) is defined according to the Committee of Antibiogram of the French company of Microbiology (CA-SFM) as being the weakest concentration which involves the inhibition of the visible bacterial growth.<sup>10</sup>

#### **3.3.1. Principle**

The determination of the minimum inhibitory concentration was carried out by the preparation of a series of dilutions of  $\frac{1}{2}$  of the antimicrobial agent to be tested on solid or liquid medium. The MIC is the lowest concentration of the antibacterial agent present in the tube, well or can which shows no visible bacterial growth.<sup>11</sup>

#### **3.3.2. Protocol**

##### **3.3.2.1. Preparation of the solutions of the stock of the chemical products**

- 32 mg of OXM was dissolved completely in 1 mL of DMSO. Then, 3 mL of medium BHI was added to obtain a final concentration of 8 mg/mL.
- 40 mg of TET was dissolved completely in 1 mL of DMSO. Then, 3 mL of medium BHI was added in order to obtain a final concentration of 10 mg/mL.

The MIC was determined by the method of dilution in liquid medium by macrodilution and microdilution using medium BHI.<sup>12</sup>

##### **3.3.2.2. Determination of the MIC by dilution in liquid medium: macrodilution**

The macrodilution method consists of preparing dilution series in test tubes with a minimum final volume of 1 mL.<sup>11</sup> Determination of the MIC of synthetic TET and OXM by macrodilution is performed according to the protocol recommended by CLSI<sup>11</sup>, with some modifications.

###### **3.3.2.2.1. Preparation of the series of dilution of products TET and OXM**

500  $\mu$ L of medium BHI was distributed in sterile test tubes. Then, 500  $\mu$ L of the solution of the stock of TET and OXM was added in the first tube. After agitation, a series of dilution in cascade was carried out by the addition of 500  $\mu$ L of the solution of the first tube to the second and so on to the last tube where 500  $\mu$ L were eliminated to have same volume in all tubes. The concentrations obtained reduced from 4 to 0.031 mg/mL for OXM and from 5 to 0.039 mg/mL for TET.

###### **3.3.2.2.2. Preparation of the inoculums**

From an 18 h old pré-culture in medium BHI of the stocks tested (*S. aureus* H, *E. coli* H, *K. pneumoniae* H, *S. aureus* A, *E. coli* A, *B. subtilis* A and *P. aeruginosa* A), a bacterial suspension is prepared in the same medium BHI.

The optical density was adjusted from 0.1 to 600 nm, which corresponds to a bacterial load of  $10^8$  CFU/mL. Then, 5 mL of the inoculum of the strains tested was prepared by adding 4.950 mL of the BHI medium and 50  $\mu$ L of the bacterial suspension in order to dilute the bacterial load by 1/100 to have a final concentration of  $10^6$  CFU/mL. 500  $\mu$ L of the bacterial inoculum was added in the tubes containing the series of dilution. The final volume in tubes is 1 mL, and the bacterial load is  $5 \times 10^5$

CFU/mL. The final concentrations reduced from 2 to 0.015 mg/mL for OXM and from 2.5 to 0.019 mg/mL for TET.

A negative control tube was realised; it contains the bacterial inoculum with  $5 \times 10^5$  CFU/mL. All tubes were incubated at 37°C for 24 h.

The MIC corresponds to the tube containing the weakest concentration of the product tested which did not show any visible bacterial growth.

### **3.3.2.3. Determination of the MIC by dilution in liquid medium: microdilution**

The microdilution method consists of preparing dilution series in a 96-well polypropylene microplate. MIC determination by microdilution was performed according to the protocol recommended by CLSI.<sup>13</sup>

#### **3.3.2.3.1. Realisation of the dilution series**

100 µL of BHI medium was distributed in all wells, except those in the first line. Then, 200 µL stock solutions of TET and OXM products were added in the first line. The dilution series was carried out by taking 100 µL of the first well from the first column and adding it to the second well belonging to the same column, until the penultimate well. The same steps were repeated for the other columns.

#### **3.3.2.3.2. Preparation of the inoculum**

The preparation of the inoculum was carried out as described above for macrodilution, except that we prepared 2 mL of the inoculum instead of 5 mL. The wells were inoculated with 100 µL of the bacterial suspension with a concentration of 10<sup>6</sup> CFU/mL. The wells in the last line of the microplate contain only the inoculum (control). The microplate was incubated at 37°C for 24 h.

The MIC corresponds to the well containing the lowest concentration of the product tested, which showed no visible bacterial growth.

### **3.4. Determination of the minimum bactericidal concentration (MBC) in solid medium**

The inhibiting minimal concentration corresponds to the weakest concentration of the product tested able to kill 99.9% of the bacteria and to let push only 0.01%.<sup>14</sup>

#### **3.4.1. Protocol**

From the tubes and wells used for the determination of the MIC, 5 µL of each tube or well was deposited on LB medium and then spread by streaks and incubated at 37°C for 24 h. The MBC was considered to be the lowest tested product concentration showing no growth.<sup>13</sup> The calculation of the MBC/MIC ratio makes it possible to evaluate whether an antibacterial agent has a bactericidal (MBC/MIC < 4) or bacteriostatic (MBC/MIC > 4) effect.<sup>15-16</sup>
